ADULT EMERGENCY MANAGEMENT 
GLYCOGEN STORAGE DISEASE TYPE 1 
(also known as glucose-6-phosphatase (GSD1a) or glucose-6-phosphate translocase (GSD1b) deficiencies) 

IMMEDIATE ACTIONS 
Triage to high priority 
Start 10% dextrose intravenously 
Please contact the patient’s metabolic team for specific advice 

These guidelines are intended for immediate emergency management only 

BACKGROUND 
Glycogen storage disease type 1 (GSD1) is a disorder of glycogen breakdown and gluconeogenesis. Adult patients with GSD1 may become hypoglycaemic if they fast for longer than about 3-4 hours: and sometimes even after a much shorter time. During illness, patients have an even greater tendency to become hypoglycaemic. Emergency treatment aims to maintain normoglycaemia all the time either with frequent oral drinks, a continuous infusion via a nasogastric tube or gastrostomy or an intravenous infusion of glucose. This management should be started as soon as patients become unwell. The early signs of decompensation may be subtle and some patients have loss of hypoglycaemic awareness and may remain asymptomatic despite marked hypoglycaemia and metabolic acidosis. Others may present with a hypoglycaemic convulsion. 

If there is any doubt at all, the patient should be admitted, even if only for a short period of observation 

INITIAL ASSESSMENT AND MANAGEMENT IN HOSPITAL 
If the patient is shocked or clearly very ill arrange for admission to ITU / HDU. 

Management decisions should be based primarily on the clinical status. If the patient is relatively well – they may be treated orally using their oral emergency regimen for GSD (generally give 200ml of a 25% glucose polymer solution every 2 hours) but assess very carefully. If the patient is obviously unwell – they must be treated with intravenous fluids. 

BIMDG_ADULT_GSD1-rev_2015
INITIAL INVESTIGATIONS
Blood pH and gases
Glucose
Urea & electrolytes
Full blood count
Liver function tests
Lactate
Other tests as clinically indicated (eg CRP, Blood & urine cultures)

TREATMENT
1. Correct hypoglycaemia initially with 50 ml of 50% dextrose over 30 minutes. If glucose cannot be quickly given intravenously then give Glucogel® into the buccal cavity. **NOTE: GSD I is NOT similar to diabetes – Glucagon does NOT work for GSD I.**

2. Start intravenous 10% dextrose as soon as possible at a rate of 2 ml/kg/hr (e.g. 140 ml/hr in a 70 kg person). Ensure normoglycaemia is maintained. **NOTE: Patients with GSD 1 can quickly become hypoglycaemic if intravenous access fails / tissues – ensure intravenous access is secure.**

3. Correct volume depletion if needed with additional 0.9% NaCl.

4. Treat any underlying infection or other clinical problem.

5. Give analgesia, anti-pyretic or an anti-emetic as required.

Acidosis can be marked but sodium bicarbonate is not given routinely. However, if acidosis persists after correction of blood glucose and perfusion, sodium bicarbonate may be needed if pH < 7.1 or pH is deteriorating rapidly or base deficit is greater than 15 mmol/L. If repeat doses of bicarbonate appear to be needed consider alternative explanations such as sepsis.

COMPLICATIONS
Other potential complications of GSD I, include: platelet dysfunction with normal count (bleeding tendency), anaemia, gout, and renal tubular wasting. Consider performing appropriate additional tests.

Patients with GSD 1b may also commonly have neutropenia with recurrent infections that may be life threatening, or a clinical presentation similar to inflammatory bowel disease.

MONITORING
Reassess frequently, including **Glasgow coma score** and blood tests:

Blood pH and gases
Urea & electrolytes: Potassium concentration should be monitored and corrected appropriately.
Lactate
Glucose Hyperglycaemia can occur. If the blood glucose consistently exceeds 10 mmol/L then reassess and either:

1) start an insulin infusion using your local protocol. Do not reduce the glucose intake.

or

2) if the patient is clinically improved and able to tolerate oral intake then reduce the rate of glucose infusion, and consider switching to their **oral emergency regimen for GSD**.

Clinical assessment should include the **Glasgow coma score** and blood pressure.
Patients should remain on iv dextrose until tolerating oral food normally. See the BIMDG oral emergency regimen for GSD for more details.
